

What is that Reddish-Pink Residue in my Toilet, Shower, or Pet's Dish?

Each year, a few Water District No. 90 customers call to ask about a slimy pink substance that sometimes forms in moist areas around their homes. They most frequently observe it in toilet bowls, on the surfaces in shower stalls, bathtub enclosures, in sinks, and in pet water dishes.

Red or pink-pigmented bacteria known as *Serratia marcescens* is thought to be the cause of the pink stuff. *Serratia* bacteria are common inhabitants of our environment and can be found in many places, including human and animal feces, dust, soil, and in surface water. The bacteria will grow in any moist location where phosphorous containing-materials or fatty substances accumulate. Sources of these substances include soap residues in bathing areas, feces in toilets, and soap and food residues in pet water dishes. *Serratia* can also grow in tap water in locations such as toilets in guest bathrooms where the water is left standing long enough for the chlorine residual disinfectant to dissipate. *Serratia marcescens* is not known to cause any waterborne diseases.

Once established, the organism usually cannot be eliminated. However, periodic and thorough cleaning of the surfaces where the pink slime occurs, followed by disinfection with chlorine bleach appear to be the best way to control it. Scrub the surfaces where phosphorus and fatty substances, or the bacteria accumulate with a brush and a household cleanser. Then disinfect the surfaces where the slime has formed with a strong chlorine bleach solution. Leave the disinfectant solution on the affected surfaces(s) for 10-20 minutes before thoroughly rinsing it away with clean water.

To control “pink stuff” in toilets, clean the bowl thoroughly and spray chlorine bleach into the bowl and under the bowl rim. Also, add ¼ cup of bleach to the toilet tank. Let the bleach stand for 15-20 minutes. After 15-20 minutes, flush the toilet a couple of times to rinse the disinfectant out of the tank and the bowl.

NOTE:

Bleach should not be left in the toilet tank for prolonged periods; it will damage the rubber valves and seals inside. Whenever a pink film starts to reappear, repeat the cleaning and disinfection process.
